

Everything in Python is cosidered to be an object, and objects have attributes and functions; when we talk about these functions with respect to these objects, we call them methods…thus, objects can have attributes and methods.

### "Strings" & [Lists]

### [List] Comprehension

Standard Method squared\_even\_numbers = [
num\*\*2 for num in nums if(num\*\*2) % 2 — (

The kind of comprehension method can be used (mutatis mutandis

### [List] & (Tuple) Manipulation

Tuples are immutable and lists are mutable; in example: — tuples cannot be appended but lists can be appended

## Decorators —

This code runs after the function

To import relative from the top level directory, use dot notation

Reference: https://github.com/Richard-Burd/python-3-sandbox

while True:
minja\_mane - imput('enter a minja\_mame:')
minja\_balt - imput('enter a balt color:')
minja\_balta[minja\_mame] - minja\_balta(

CONTINUE)

{Dictionary} Comprehension

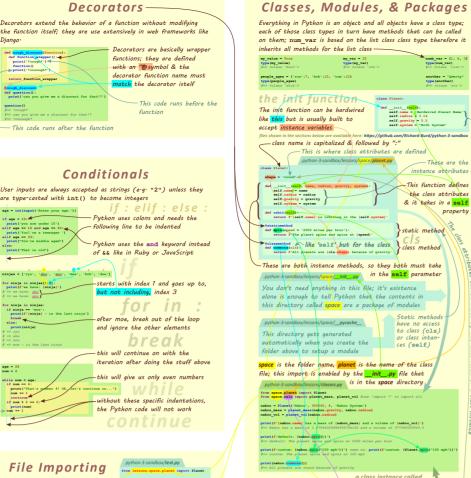

substitute for loops and lambda functions: However, not all for loops can be written as a dictionary comprehension but all dictionary comprehensions can be written with a for loop.

ir.k: (inner\_v)
r (inner\_k, inner\_v) in outer\_v.items() if inner\_k == 'name' }
for (outer\_k, outer\_v) in people\_dictionary.items()

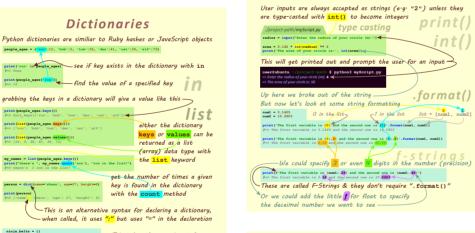

— this keeps the code execution in the while loop when the user enters in "y"

— Identify odd and even entries

Conditionals

# Console Inputs & Strings

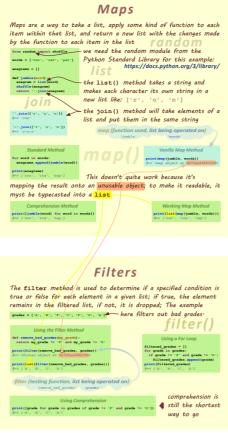

## Ranges

In Python, ranges generate a list of numbers for us that we can then use to iterate over in for loops for a in range(5):

this will go up to but not including 5 go through but not include 10 for n in range(20,300, 80):

# print(n)
#-> 20 #-> 100 #-> 180 #-> this will **start** from and include 20 and go through but not <mark>includ</mark> 300 in intervals of 80 len() this len() method times one length of the names list and some length of th

and a doctor"	if True   False: if False   True: if False   F
},	print("truthy") print("truthy") print("tru
3	else: else: else: else: print("falsey") print("falsey") print("fal
	#=> truthy #=> truthy #=> falsey

## Collections - Deque

x.rotate(2) print(x) \$-> deque(['6', '1', '2', '3 v.stand([1, 2, 3]) print(w) 2 3 4 3 for demaif(a', 'a', 1, 2, 3], maxlen=5) you can only add to the deque with the extend() method, but that will still mantain the original maxlen of 5

{Sets} [Lists] & Sorting

all code shamm in this section is available here: https://github.com/Rikhard-Bund/pythan-3-sandbau/sets.py Python lists are similiar to JavaScript & Ruby arrays whereas Python sets are essentially Python dictionaries with only keys, and no values: Every element in a set must be immutable but the set

set and thus, remove duplicates in a list of strings, but it will not

with capital letters

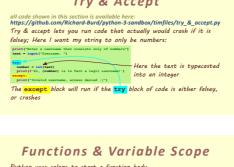

keys values

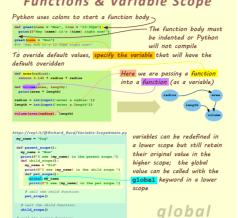

this -1 is the last item in the list and the start position, this -1 is the position right before the start of the list because this value tells us the looping and point and it is an up-to-but-not-include value, finally, this -2 is the increment amount, and it is negative

## Dictionary Iteration

## Trv & Accept

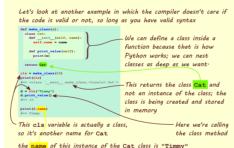

## **Advanced Overview Features**

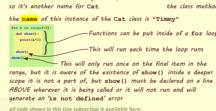

https://ghthub.com/kichard-Burd/python-3-sandbox/kinfiles/expert.py
Python is compiled into bytecode before it is interpreted
Compilers take high-level code and translate it into a lower-levelAn interpreter takes some kind of code, in our case bytecode, and
interprete & runs that code: This is unique to Python because it
is a compiled language, here we have a class with an undefined

" compiled language, here we have a class with an undefined

'bark' method:

| This is unique to Python because it is a compiled language, here we have a class with an undefined language, here we have a class with an undefined bark' method that has not yet been defined; If I run the code at this point there will be no errors. In other languages, the compiler would detect this error and tell you to define what 'bark' is, but here, this bit of code is executed at runtime instead of compile time. All the compiler does for us is translate the Python into bytecode, and it does not always check to see if the code is actually valid. Thus, the error above is said to be 'only caught at runtime' and not at compile time.

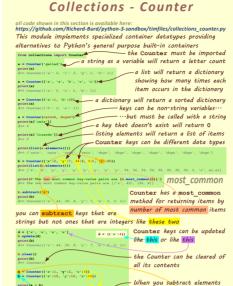

## Zip Function

nce: https://www.w3schools.com/python/ref\_func\_zip.asp

## Collections

Here we say that b is "intersecting" with a and this gives the lowest common values for the items in the counter, in this case, z has a value of 3 (in Counter a above) and a value of 10 (in Counter b above) so since 3 is the smallest, that is the intersect value intersection & union of Counters

The opposite of intersecting is called "union" (x & y) which is shown here: These are the maximum values between the two Counters a and b above  $(x \mid y)$ 

Reading Files

Lambdas

lambda x, y, z: n\*n

[ambda (first variable, second variable: calculation)]

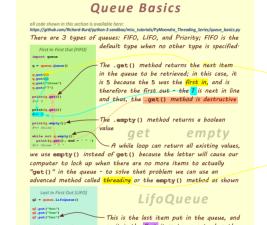

— You could pass in multiple arguments into a lambda like this

ad.py this opens an external file at:
.python-3-sandbox/lessons/files/lpsum.py

using with open () as: is generally better than using the seperate open () & close () statements shown above; the file remains open while code beneath is indemed and closes when the code indentation ends

Python allows you to open up files and read them then do

on a counter, it will not show values of 0 or negative values

Collections - NamedTuple

when the a capitalized string and the item names are declared in the second string with each item separated by a space

with the \_replace() method, but this is not destructive, in other words, we need to assign a new value to the operation because we cannot change the original namedtuple in this way.

Data class and this new instance will have the specified values passed into the make() method· NOTE: the values are now strings, not integers as in the original declaration above, because we can change the data type

in a dictionary

\_\_\_\_\_values can be converted to a dictionary with
the \_asdict() method

with the fields() method

Named tuples allow for the use of dot notation, but regular tuples do not

## Writing Files

## **Downloading Files**

and this statement gets printed out

**Dunder Magic** 

call method will handle that call for the Person class These are all data model methods data model methods

from queue import Queue as q apport Laspect La

Threading

importing of the threading module

\_\_\_\_ By default we get the memory

length (len) is called on the Person class; in this example, the string "four"

Oueue

calling the print
method on the
declaration, we get
something meaningful t
